# Problem Set 7

**Both theory and programming questions** are due on **Tuesday, December 6** at **11:59PM**. Please download the .zip archive for this problem set. Refer to the README.txt file for instructions on preparing your solutions.

We will provide the solutions to the problem set 10 hours after the problem set is due. You will have to read the solutions, and write a brief **grading explanation** to help your grader understand your write-up. You will need to submit the grading guide by **Thursday, December 8, 11:59PM**. Your grade will be based on both your solutions and the grading explanation.

**Collaborators:** None.

**Problem 7-1.** [30 points] **Seam Carving**

In a recent paper, "Seam Carving for Content-Aware Image Resizing", Shai Avidan and Ariel Shamir describe a novel method of resizing images. You are welcome to read the paper, but we recommend starting with the YouTube video:

<center>http://www.youtube.com/watch?v=vIFCV2spKtg</center>

Both are linked from the Problem Sets page on the class website. After you've watched the video, the terminology in the rest of this problem will make sense.

If you were paying attention around time 1:50 of the video, then you can probably guess what you're going to have to do. You are given an image, and your task is to calculate the best vertical seam to remove. A *vertical seam* is a connected path of pixels, one pixel in each row. We call two pixels *connected* if they are vertically or diagonally adjacent. The *best* vertical seam is the one that minimizes the total "energy" of pixels in the seam.

The video didn't spend much time on dynamic programming, so here's the algorithm:

**Subproblems:** For each pixel $(i, j)$, what is the lower-energy seam that starts at the top row of the image, but ends at $(i, j)$?

**Relation:** Let dp[i,j] be the solution to subproblem $(i, j)$. Then
dp[i,j] = min(dp[i,j-1],dp[i-1,j-1],dp[i+1,j-1]) + energy(i,j)

**Analysis:** Solving each subproblem takes $O(1)$ time: there are three smaller subproblems to look up, and one call to energy(), which all take $O(1)$ time. There is one subproblem for each pixel, so the running time is $\Theta(A)$, where $A$ is the number of pixels, i.e., the area of the image.

Download ps7_code.zip and unpack it. To solve this problem set, you will need the Python Imaging Library (PIL), which you should have installed for Problem Set 4. If you wish to view your results, you will additionally need the Tkinter library.

In `resizeable_image.py`, write a function `best_seam(self)` that returns a list of coordinates corresponding to the cheapest vertical seam to remove, e.g., $[(5,0), (5,1), (4,2), (5,3), (6,4)]$. You should implement the dynamic program described above in a bottom-up manner.

The class `ResizeableImage` inherits from `ImageMatrix`. You should use the following components of `ImageMatrix` in your dynamic program:

- `self.energy(i,j)` returns the energy of a pixel. This takes $O(1)$ time, but the constant factor is sizeable. If you call it more than once, you might want to cache the results.

- `self.width` and `self.height` are the width and height of the image, respectively.

Test your code using `test_resizable_image.py`, and submit `ResizeableImage.py` to the class website. You can also view your code in action by running `gui.py`. Included with the problem set are two differently sized versions of the same sunset image. If you remove enough seams from the sunset image, it should center the sun.

Also, please try out your own pictures (most file formats should work), and send us any interesting before/after shots.

**Problem 7-2.** [70 points] **HG Fargo**

You have been given an internship at the extremely profitable and secretive bank HG Fargo. Your immediate supervisor tells you that higher-ups in the bank are very interested in learning from the past. In particular, they want to know how much money they *could* have made if they had invested optimally.

Your supervisor gives you the following data on the prices[1] of select stocks in 1991 and in 2011:

| Company | Price in 1991 | Price in 2011 |
|---|---|---|
| Dale, Inc. | $12 | $39 |
| JCN Corp. | $10 | $13 |
| Macroware, Inc. | $18 | $47 |
| Pear, Inc. | $15 | $45 |

As a first step, you decide to examine what the optimal decision is for a couple of small examples:

(a) [5 points] If you had $20 available to purchase stocks in 1991, how much of each stock should you have bought to maximize profits when you sell everything in 2011? Note that you do not need to invest all of your money — if it is more profitable to keep some as cash, you do not need to invest it.

**Answer:**

| Company | Number of Shares |
|---|---|
| Dale, Inc. | 0 |
| JCN Corp. | 0 |
| Macroware, Inc. | 0 |
| Pear, Inc. | 1 |

(b) [5 points] If you had $30 available to purchase stocks in 1991, how much of each stock should you have bought?

**Answer:**

| Company | Number of Shares |
|---|---|
| Dale, Inc. | 0 |
| JCN Corp. | 0 |
| Macroware, Inc. | 0 |
| Pear, Inc. | 2 |

(c) [5 points] If you had $120 available to purchase stocks in 1991, how much of each stock should you have bought?

**Answer:**

---

[1]Note that for the purposes of this problem, you should ignore some of the intricacies of the real stock market. The only income you can make is from purchasing stocks in 1991, then selling those same stocks at market value in 2011.

| Company | Number of Shares |
|---|---|
| Dale, Inc. | 10 |
| JCN Corp. | 0 |
| Macroware, Inc. | 0 |
| Pear, Inc. | 0 |

Your supervisor asks you to write an algorithm for computing the best way to purchase stocks, given the initial money *total*, the number *count* of companies with stock available, an array *start* containing the prices of each stock in 1991, and an array *end* containing the prices of each stock in 2011. All prices are assumed to be positive integers.

There is a strong relationship between this problem and the knapsack problem. The knapsack problem takes four inputs: the number of different items *items*, the item sizes *size* (all of which are integers), the item values *value* (which may not be integers), and the size *capacity* of the knapsack. The goal is to pick a subset of the items that fits inside the knapsack and maximizes the total value.

**(d)** [1 point]  Which input to the knapsack problem corresponds to the input *total* in the stock purchasing problem?

    1. *items*        2. *size*        3. *value*        4. *capacity*

    **Answer:**  The answer is 4. 'total' variable can be seen as capacity. We can buy shares as long as our total money/capacity is enough

**(e)** [1 point]  Which input to the knapsack problem corresponds to the input *count* in the stock purchasing problem?

    1. *items*        2. *size*        3. *value*        4. *capacity*

    **Answer:**  The answer is 1. 'count' variable represents number of stock type i.e. items

**(f)** [1 point]  Which input to the knapsack problem corresponds to the input *start* in the stock purchasing problem?

    1. *items*        2. *size*        3. *value*        4. *capacity*

    **Answer:**  The answer is 2. 'start' array stores the initial costs of the stocks i.e. size of items.

**(g)** [1 point]  Which input to the knapsack problem corresponds to the input *end* in the stock purchasing problem?

    1. *items*        2. *size*        3. *value*        4. *capacity*

    **Answer:**  The answer is 3. 'end' array stores the last prices of the stocks i.e. value of items.

**(h)** [6 points] Unfortunately, the algorithm for the knapsack problem cannot be directly applied to the stock purchasing problem. For each of the following potential reasons, state whether it's a valid reason not to use the knapsack algorithm. (In other words, if the difference mentioned were the only difference between the problems, would you still be able to use the knapsack algorithm to solve the stock purchasing problem?)

1. In the stock purchasing problem, there is a time delay between the selection and the reward.
2. All of the numbers in the stock purchasing problem are integers. The *value* array in the knapsack problem is not.
3. In the stock purchasing problem, the money left over from your purchases is kept as cash, which contributes to your ultimate profit. The knapsack problem has no equivalent concept.
4. In the knapsack problem, there are some variables representing sizes of objects. There are no such variables in the stock purchasing problem.
5. In the stock purchasing problem, you can buy more than one share in each stock.
6. In the stock purchasing problem, you sell all the items at the end. In the knapsack problem, you don't do anything with the items.

**Answer:** 1. False. The main problem asks what would be the profit if money had spent in 1991 to buy stocks so time delay won't be a problem for using knapsack as long as we know the initial costs and values in 2011 of stocks.

2. False. Knapsack can be used with integers so this statement is wrong

3. True. Knapsack has no equivalent concept and remained capacity can't be added to the total value of the chosen items. However, a modified version of the knapsack still can be used to solve stock purchasing problem by treating 'total' variable as capacity and value at the same time.

4. False. Prices of the stocks in 1991 are initial costs are initial costs (stored in 'start' array) and can be used as sizes of objects in knapsack.

5. True. Knapsack has no equivalent concept. Any of the items can be used only one time.

6. False. Problem asks what would be the maximum profit if all of the items had sold i.e. sum of the values of the items at the end of the process. (Values of the stocks stored in 'end' array)

Despite these differences, you decide that the knapsack algorithm is a good starting point for the problem you are trying to solve. So you dig up some pseudocode for the knapsack problem, relabel the variables to suit the stock purchasing problem, and then start modifying things. After a long

night of work, you end up with a couple of feasible solutions. Unfortunately, there is a bit of a hard-drive error the next morning, and the files are all mixed up. You have recovered six different functions, from various states in your development process. The first function is the following:

STOCK(*total*, *count*, *start*, *end*)

1   *purchase* = STOCK-TABLE(*total*, *count*, *start*, *end*)
2   **return** STOCK-RESULT(*total*, *count*, *start*, *end*, *purchase*)

This is the function that you ran to get your results. The STOCK-TABLE function generates the table of subproblem solutions. The STOCK-RESULT function uses that to figure out which stocks to purchase, and in what quantities. Unfortunately, you have two copies of the STOCK-TABLE function and three copies of the STOCK-RESULT function. You know that there's a way to take one of each function to get the pseudocode for the original knapsack problem (with the names changed). You also know that there's a way to take one of each function to get the pseudocode for the stock purchases problem. You just don't know which functions do what.

Analyze each of the other five procedures, and select the correct running time. Recall that *total* and *count* are positive integers, as are each of the values *start*[*stock*] and *end*[*stock*]. To make the code simpler, the arrays *start*, *end*, and *result* are assumed to be indexed starting at 1, while the tables *profit* and *purchase* are assumed to be indexed starting at $(0, 0)$. You may assume that entries in a table can be accessed and modified in $\Theta(1)$ time.

**(i)** [1 point] What is the worst-case asymptotic running time of STOCK-TABLE-A (from Figure 1) in terms of *count* and *total*?

1. $\Theta(count)$
2. $\Theta(count^2)$
3. $\Theta(count^3)$
4. $\Theta(total)$
5. $\Theta(total^2)$
6. $\Theta(total^3)$

7. $\Theta(count + total)$
8. $\Theta(count^2 + total)$
9. $\Theta(count + total^2)$
10. $\Theta(count \cdot total)$
11. $\Theta(count^2 \cdot total)$
12. $\Theta(count \cdot total^2)$

**Answer:**   The answer is $\Theta$(count * total). The loop in the line 3 repeats total times and the loop in the line 6 ,which is in cash = 0 to total loop, repeats count times. Each operation between line 3 to line 14 takes $\Theta(1)$ time.

**(j)** [1 point] What is the worst-case asymptotic running time of STOCK-TABLE-B (from Figure 2) in terms of *count* and *total*?

STOCK-TABLE-A($total, count, start, end$)

```
 1   create a table profit
 2   create a table purchase
 3   for cash = 0 to total
 4       profit[cash, 0] = cash
 5       purchase[cash, 0] = FALSE
 6       for stock = 1 to count
 7           profit[cash, stock] = profit[cash, stock − 1]
 8           purchase[cash, stock] = FALSE
 9           if start[stock] ≤ cash
10               leftover = cash − start[stock]
11               current = end[stock] + profit[leftover, stock]
12               if profit[cash, stock] < current
13                   profit[cash, stock] = current
14                   purchase[cash, stock] = TRUE
15   return purchase
```

**Figure 1**: The pseudocode for STOCK-TABLE-A.

STOCK-TABLE-B($total, count, start, end$)

```
 1   create a table profit
 2   create a table purchase
 3   for cash = 0 to total
 4       profit[cash, 0] = 0
 5       purchase[cash, 0] = FALSE
 6       for stock = 1 to count
 7           profit[cash, stock] = profit[cash, stock − 1]
 8           purchase[cash, stock] = FALSE
 9           if start[stock] ≤ cash
10               leftover = cash − start[stock]
11               current = end[stock] + profit[leftover, stock − 1]
12               if profit[cash, stock] < current
13                   profit[cash, stock] = current
14                   purchase[cash, stock] = TRUE
15   return purchase
```

**Figure 2**: The pseudocode for STOCK-TABLE-B.

1. $\Theta(count)$
2. $\Theta(count^2)$
3. $\Theta(count^3)$
4. $\Theta(total)$
5. $\Theta(total^2)$
6. $\Theta(total^3)$

7. $\Theta(count + total)$
8. $\Theta(count^2 + total)$
9. $\Theta(count + total^2)$
10. $\Theta(count \cdot total)$
11. $\Theta(count^2 \cdot total)$
12. $\Theta(count \cdot total^2)$

**Answer:** The answer is $\Theta$(count * total). The loop in the line 3 repeats total times and the loop in the line 6 ,which is in cash = 0 to total loop, repeats count times. Each operation between line 3 to line 14 takes $\Theta(1)$ time. (The only difference between STOCK-TABLE codes is the Line 4 and line 11.

**(k)** [1 point] What is the worst-case asymptotic running time of STOCK-RESULT-A (from Figure 3) in terms of *count* and *total*?

1. $\Theta(count)$
2. $\Theta(count^2)$
3. $\Theta(count^3)$
4. $\Theta(total)$
5. $\Theta(total^2)$
6. $\Theta(total^3)$

7. $\Theta(count + total)$
8. $\Theta(count^2 + total)$
9. $\Theta(count + total^2)$
10. $\Theta(count \cdot total)$
11. $\Theta(count^2 \cdot total)$
12. $\Theta(count \cdot total^2)$

**Answer:** The answer is $\Theta$(count). Table creating process in line 1 takes $\Theta$(count) time. The loop in line 2 and the loop in line 7 repeat count times. All other operations take $\Theta(1)$ time

**(l)** [1 point] What is the worst-case asymptotic running time of STOCK-RESULT-B (from Figure 4) in terms of *count* and *total*?

1. $\Theta(count)$
2. $\Theta(count^2)$
3. $\Theta(count^3)$
4. $\Theta(total)$
5. $\Theta(total^2)$
6. $\Theta(total^3)$

7. $\Theta(count + total)$
8. $\Theta(count^2 + total)$
9. $\Theta(count + total^2)$
10. $\Theta(count \cdot total)$
11. $\Theta(count^2 \cdot total)$
12. $\Theta(count \cdot total^2)$

**Answer:** The answer is $\Theta$(count). Table creating process in line 1 takes $\Theta$(count) time. The loop in line 2 and the loop in line 7 repeat count times. All other operations take $\Theta(1)$ time

**(m)** [1 point] What is the worst-case asymptotic running time of STOCK-RESULT-C (from Figure 5) in terms of *count* and *total*?

STOCK-RESULT-A($total, count, start, end, purchase$)

```
 1   create a table result
 2   for stock = 1 to count
 3       result[stock] = 0
 4
 5   cash = total
 6   stock = count
 7   while stock > 0
 8       quantity = purchase[cash, stock]
 9       result[stock] = quantity
10       cash = cash − quantity · start[stock]
11       stock = stock − 1
12
13   return result
```

**Figure 3**: The pseudocode for STOCK-RESULT-A.

STOCK-RESULT-B($total, count, start, end, purchase$)

```
 1   create a table result
 2   for stock = 1 to count
 3       result[stock] = FALSE
 4
 5   cash = total
 6   stock = count
 7   while stock > 0
 8       if purchase[cash, stock]
 9           result[stock] = TRUE
10           cash = cash − start[stock]
11       stock = stock − 1
12
13   return result
```

**Figure 4**: The pseudocode for STOCK-RESULT-B.

STOCK-RESULT-C(*total, count, start, end, purchase*)

```
1   create a table result
2   for stock = 1 to count
3       result[stock] = 0
4
5   cash = total
6   stock = count
7   while stock > 0
8       if purchase[cash, stock]
9           result[stock] = result[stock] + 1
10          cash = cash − start[stock]
11      else
12          stock = stock − 1
13
14  return result
```

**Figure 5**: The pseudocode for STOCK-RESULT-C.

1. $\Theta(count)$
2. $\Theta(count^2)$
3. $\Theta(count^3)$
4. $\Theta(total)$
5. $\Theta(total^2)$
6. $\Theta(total^3)$
7. $\Theta(count + total)$
8. $\Theta(count^2 + total)$
9. $\Theta(count + total^2)$
10. $\Theta(count \cdot total)$
11. $\Theta(count^2 \cdot total)$
12. $\Theta(count \cdot total^2)$

**Answer:** The answer is $\Theta(count + total)$. Table creating process in line 1 takes $\Theta(count)$ time. The loop in line 2 repeats count times. However, the loop in line 7 may repeat count + total times based on the if - else conditions. All other operations inside the loops take $\Theta(1)$ time.

**(n)** [2 points] The recurrence relation computed by the STOCK-TABLE-A function is:

1. $profit[c, s] = \max\{profit[c, s − 1], profit[c − start[s], s − 1]\}$
2. $profit[c, s] = \max\{profit[c, s − 1], profit[c − start[s], s − 1] + end[s]\}$
3. $profit[c, s] = \max_q\{profit[c − q \cdot start[s], s − 1] + q \cdot end[s]\}$
4. $profit[c, s] = \max\{profit[c, s − 1], profit[c − start[s], s]\}$
5. $profit[c, s] = \max\{profit[c, s − 1], profit[c − start[s], s] + end[s]\}$
6. $profit[c, s] = \max_q\{profit[c − q \cdot start[s], s] + q \cdot end[s]\}$

**Answer:** The answer is 5. In line 7 of the STOCK-TABLE-A $profit[c, s - 1]$ value is stored and in line 11 $profit[c - start[s], s] + end[s]\}$ value is stored. In line 12 following relation are used using stored values:

$$profit[c, s] = \max\{profit[c, s - 1], profit[c - start[s], s] + end[s]\}$$

**(o)** [2 points] The recurrence relation computed by the STOCK-TABLE-B function is:

1. $profit[c, s] = \max\{profit[c, s - 1], profit[c - start[s], s - 1]\}$
2. $profit[c, s] = \max\{profit[c, s - 1], profit[c - start[s], s - 1] + end[s]\}$
3. $profit[c, s] = \max_q\{profit[c - q \cdot start[s], s - 1] + q \cdot end[s]\}$
4. $profit[c, s] = \max\{profit[c, s - 1], profit[c - start[s], s]\}$
5. $profit[c, s] = \max\{profit[c, s - 1], profit[c - start[s], s] + end[s]\}$
6. $profit[c, s] = \max_q\{profit[c - q \cdot start[s], s] + q \cdot end[s]\}$

**Answer:** The answer is 2. In line 7 of the STOCK-TABLE-B $profit[c, s - 1]$ value is stored and in line 11 $profit[c - start[s], s - 1] + end[s]\}$ value is stored. In line 12 following relation are used using stored values:

$$profit[c, s] = \max\{profit[c, s - 1], profit[c - start[s], s - 1] + end[s]\}$$

With this information, you should be able to figure out whether STOCK-TABLE-A or STOCK-TABLE-B is useful for the knapsack problem, and similarly for the stock purchasing problem. From there, you can figure out which of STOCK-RESULT-A, STOCK-RESULT-B, and STOCK-RESULT-C is best for piecing together the optimal distribution of stocks and/or items.

**(p)** [3 points] Which two methods, when combined, let you compute the answer to the knapsack problem?

1. STOCK-TABLE-A and STOCK-RESULT-A
2. STOCK-TABLE-A and STOCK-RESULT-B
3. STOCK-TABLE-A and STOCK-RESULT-C
4. STOCK-TABLE-B and STOCK-RESULT-A
5. STOCK-TABLE-B and STOCK-RESULT-B
6. STOCK-TABLE-B and STOCK-RESULT-C

**Answer:** The answer is 5. STOCK-TABLE-B has same logic with knapsack. Each item is used one time. STOCK-RESULT-B can be used to create the purchase list because it evaluates each item as taken or not taken, just like in knapsack.

**(q)** [3 points] Which two methods, when combined, let you compute the answer to the stock purchases problem?

1. STOCK-TABLE-A and STOCK-RESULT-A

2. STOCK-TABLE-A and STOCK-RESULT-B

3. STOCK-TABLE-A and STOCK-RESULT-C

4. STOCK-TABLE-B and STOCK-RESULT-A

5. STOCK-TABLE-B and STOCK-RESULT-B

6. STOCK-TABLE-B and STOCK-RESULT-C

**Answer:** The answer is 3. STOCK-TABLE-A allows multiple purchase for each stock. STOCK-RESULT-C can be used to create the purchase list because it evaluates each item based on quantity.

With all that sorted out, you submit the code to your supervisor and pat yourself on the back for a job well done. Unfortunately, your supervisor comes back a few days later with a complaint from the higher-ups. They've been playing with your program, and were very upset to discover that when they ask what to do with $1,000,000,000 in the year 1991, it tells them to buy tens of millions of shares in Dale, Inc. According to them, there weren't that many shares of Dale available to purchase. They want a new feature: the ability to pass in limits on the number of stocks purchaseable.

You choose to begin, as always, with a small example:

| Company | Price in 1991 | Price in 2011 | Limit |
|---|---|---|---|
| Dale, Inc. | $12 | $39 | 3 |
| JCN Corp. | $10 | $13 | $\infty$ |
| Macroware, Inc. | $18 | $47 | 2 |
| Pear, Inc. | $15 | $45 | 1 |

**(r)** [5 points] If you had $30 available to purchase stocks in 1991, how much of each stock should you have bought, given the limits imposed above?

**Answer:**

| Company | Number of Shares |
|---|---|
| Dale, Inc. | 1 |
| JCN Corp. | 0 |
| Macroware, Inc. | 0 |
| Pear, Inc. | 1 |

**(s)** [5 points] If you had $120 available to purchase stocks in 1991, how much of each stock should you have bought, given the limits imposed above?

**Answer:**

| Company | Number of Shares |
|---|---|
| Dale, Inc. | 3 |
| JCN Corp. | 3 |
| Macroware, Inc. | 2 |
| Pear, Inc. | 1 |

**(t)** [20 points]  Give pseudocode for an algorithm STOCKLIMITED that computes the maximum profit achievable given a starting amount $total$, a number $count$ of companies with stock available, an array of initial prices $start$, an array of final prices $end$, and an array of quantities $limit$. The value stored at $limit[stock]$ will be equal to $\infty$ in cases where there is no known limit on the number of stocks. The algorithm need only output the resulting quantity of money, not the purchases necessary to get that quantity.

Remember to analyze the runtime of your pseudocode, and provide a brief justification for its correctness. It is sufficient to give the recurrence relation that your algorithm implements, and talk about why the recurrence relation solves the problem at hand.

**Answer:**  STOCK-TABLE-A can be modified to solve limited stock stock purchase problem. Following modifications can be made to modify STOCK-TABLE-A function:

1) Since we don't need to create a purchase list, we don't need to use purchase table so lines 2, 5, 8 and 14 can be removed

2) We have a new constraint which is the purchase limit of the stocks. We can use knapsack logic in this code by taking different quantities of the same stock to find most profitable buying option. In this case we need an additional loop which have variable range based on the total cash at hand:

a) If int(cash/start[stock]) ¡ limit[stock], we are bounded by the cash at hand so upper bound of the loop will be int(cash/start[stock])

b) Otherwise, we are bounded by the limit[stock] so upper bound of the loop will be limit[stock]

Notice that check in Line 9 is removed because we do this check when upper bound of the loop are determined.

3) Also, we need to use knapsack logic: Decide how many stock to buy then move on to the next stock. Therefore, line 11 will be as follows:

$$current = quantity * end[stock] + profit[leftover, stock - 1]$$

In the line of these, final limited stock purchase code will be as follows:

STOCKLIMITED($total, count, start, end, limit$)

```
 1   create a table profit
 2   for cash = 0 to total
 3       profit[cash][0] = cash
 4       for stock = 1 to count
 5           profit[cash][stock] = profit[cash][stock - 1]
 6           for quantity = 1 to min(limit[stock], int(cash/start[stock]))
 7               leftover = cash - quantity * start[stock]
 8               current = quantity * end[stock] + profit[leftover][stock - 1]
 9               if profit[cash][stock] < current
10                   profit[cash][stock] = current
11   return profit[total][count]
```

The recurrence relation for this code will be as follows:

$$upperbound = \min\{c(limit[stock], \frac{cash}{start[stock]})\}$$

$$profit[c, s] = \max\{profit[c, s - 1], profit[c - q \cdot start[s], s - 1] + q \cdot end[s] \\ for \; q = 1 \; to \; upperbound\}$$
